

Python GUI Course for Absolute Beginners Learn the Fun, Visual Way

This course is designed for students who know nothing about Python and want to start learning in a visual and motivating way. Instead of beginning with theory, you will immediately create graphical interfaces (GUI) and gradually understand how Python works.

What You Will Learn (Without Stress)

- 1 Create windows and message boxes
- 2 Control window size and title
- 3 Add text and buttons
- 4 Make buttons react to user actions
- 5 Naturally introduce Python logic later

Step 0 – Setup (One Time Only)

1. Install Python

Download Python 3 from python.org and check *Add Python to PATH* during installation.

2. Choose an Editor

Use VS Code or IDLE (included with Python).

Exercise 1 – Your First GUI: Message Box

Goal: Display a message on the screen using Python.

Code:

```
from tkinter import messagebox  
  
messagebox.showinfo("Hello!", "Welcome to your first Python GUI ■")
```

This code directly opens a message box. You already created a GUI without a window.

Exercise 2 – Create Your First Window

Goal: Open an empty application window.

Code:

```
import tkinter as tk  
  
window = tk.Tk()  
window.mainloop()
```

Tk() creates the window. mainloop() keeps it running. Every GUI application needs it.

Exercise 3 – Customize Window Size and Title

Goal: Make the window personal.

Code:

```
import tkinter as tk

window = tk.Tk()
window.title("My First App ■")
window.geometry("400x300")

window.mainloop()
```

You changed the title and defined the window size (width x height).

Exercise 4 – Display Text in the Window

Goal: Show text inside the GUI.

Code:

```
import tkinter as tk

window = tk.Tk()
window.title("My App")
window.geometry("400x300")

label = tk.Label(window, text="Hello World ■", font=("Arial", 16))
label.pack()

window.mainloop()
```

Labels are used to display text. `pack()` places elements automatically inside the window.

Exercise 5 – Add Your First Button

Goal: Add a clickable button.

Code:

```
import tkinter as tk

window = tk.Tk()
window.title("Button App")
window.geometry("400x300")

button = tk.Button(window, text="Click Me")
button.pack()

window.mainloop()
```

You created your first button. It does nothing yet, but it is fully functional.

Exercise 6 – Button with Action

Goal: Make the button react when clicked.

Code:

```
import tkinter as tk
from tkinter import messagebox

def say_hello():
    messagebox.showinfo("Hi", "You clicked the button ■")

window = tk.Tk()
window.title("Smart Button")
window.geometry("400x300")

button = tk.Button(window, text="Click Me", command=say_hello)
button.pack()

window.mainloop()
```

The command option links a button to a function. This is how interaction works in GUIs.

Mini Challenges

- 1 Change the text on the button
- 2 Modify the window size
- 3 Add a second button to close the application

What Comes Next

- 1 Colors and visual styling
- 2 Using variables (counters, scores)
- 3 if statements for decisions
- 4 Better layouts (grid, place)
- 5 Small projects: calculator, login screen, simple games
